This publication represents the views and expert opinions of an IARC Working Group on the Evaluation of Cancer-Preventive Interventions, which met in Lyon, 5–12 April 2016.
2.2.6 Cancers of the biliary tract

Intrahepatic bile duct cancers occur in the smaller bile duct branches within the liver and comprise about 10% of bile duct cancers. Extrahepatic bile duct cancers occur outside of the liver. Perihilar (also called hilar) extrahepatic bile duct cancers occur where the left and right hepatic ducts join and are the most common type of bile duct cancer, accounting for about two thirds of all bile duct cancers. Nearly all bile duct cancers are cholangiocarcinomas, of which most are adenocarcinomas. This section reviews studies of all subtypes of cancer of the biliary tract.

(a) Cohort studies

See Table 2.2.6a (web only; available at: http://publications.iarc.fr/570).

Only one prospective study (i.e. the EPIC cohort) assessed the association between body weight and intrahepatic bile duct cancer specifically; relative risk estimates for all measurements (BMI, weight, waist or hip circumference, waist-to-hip ratio, or weight change) as continuous measures were greater than 1, but none of the associations were statistically significant (Ishiguro et al., 2008).

The association between BMI and extrahepatic bile duct cancer specifically (excluding the gall bladder) was examined in the Japan Public Health Center Study. In that study, BMI was positively associated with risk in men and women combined, with a relative risk of 1.78 for BMI ≥ 27 kg/m² compared with < 23 kg/m² ($P_{trend} = 0.03$) (Ishiguro et al., 2008).

The association between BMI and extrahepatic bile duct cancer was examined in the Korea National Health Insurance Corporation Study, which included only men and found a statistically significant positive dose–response relationship ($P_{trend} = 0.005$) (Oh et al., 2005).

(b) Case–control studies

See Table 2.2.6b (web only; available at: http://publications.iarc.fr/570).

The associations of BMI with cancers of the biliary tract system (including gall bladder or not) were examined in six population- or hospital-based case–control studies.

For extrahepatic bile duct cancer, two population-based case–control studies, one in Europe (Ahrens et al., 2007) and one in China (Hsing et al., 2008), showed a statistically significant higher risk for BMI > 25 kg/m² versus 18.5–25 kg/m², whereas a lower risk with high BMI was observed in one study in China (Kato et al., 1989). No association was observed in a study of cholangiocarcinoma (Grainge et al., 2009). No association was observed with waist circumference in the only study that examined such association (Shebl et al., 2011).
For overall biliary tract cancer, a 2.5-fold increase in risk was observed with BMI \(\geq 30\) kg/m\(^2\) at age 35 years, but not with BMI 1–5 years before study entry (Ahrens et al., 2007).
